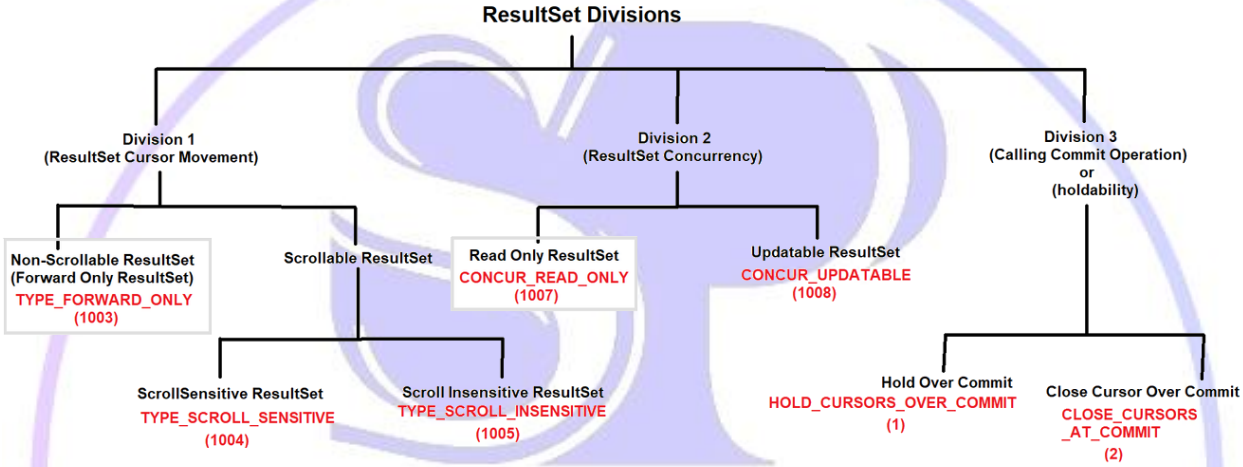
An investment in Knowledge pays the best interest….

JDBC (PART 10)

⇨ Types Of ResultSet



⇨ Difference between Non-Scrollable (Forward Only) & Scrollable ResultSet

1. In Non-Scrollable the Cursor can move only in forward dierction i.e. from 1st position to last position

In Scrollable the cursor can move in any direction, eith forward or backword or to any specific row

2. In Non-Scrollable the cursor cant move randomly

   In Scrollable, the cursor can move randomly

3. The performance of Non-Scrollable is slow because we have to traverse the data form top to bottom

   The performance of Scrollable cursor is fast as it can move randomly

⇨ Difference between Scroll-Insensitive and Scroll Sensitive

1. Scroll-insensitive is insensitive to database which means after getting resultset object, if we perform any change in Database, it will not be reflected to resultset object.

   Scroll-sensitive is sensitive to database which means after getting resultset object if we perform any changes in database, it will be reflected to resultset object automatically

2. The performance of Scroll-Insensitive is high

   The performance of Scroll-Sensitive is low because there is regular connection between database and resultset object.
