An investment in Knowledge pays the best interest….

JDBC (PART 7)

CallableStatement:-

It is an interface present in java.sql package

Syntax :

```
interface Statement
{
    //methods
}
interface PreparedStatement extends
                                Statement
{
    //methods
}
interface CallableStatement extends
                                PreparedStatement
```

```
{
    //methods
}
```

Methods:

1. execute()
2. executeUpdate()
3. executeQuery()
4. setInt()
5. setString()
6. setXxx()
7. registerOutParameter()
8. addBatch()
9. removeBatch()
10. close() etc….

Use :-

- CallableStatement are used to call stored procedure or functions.
- By using CallableStatement the performance of application is increased

---

Stored Procedure :-

- It is a prepared SQL query/code that is saved at database side so that we can use it again and again
- We need not to compile the query again and again, we have to call it directly
- Types of Parameters:-
  1. IN : It will take values from procedure call to procedure body

2. OUT : It will take values from procedure body to procedure call

3. INOUT : It acts as both In & OUT type parameter

Stored Procedure Queries :-

⇨ **Query to check all existing procedures**

SHOW PROCEDURE STATUS

⇨ **TO delete any stored procedure**

DROP PROCEDURE procedureName;

⇨ **Create Stored Procedure**

DELIMITER //

⇨ Query without any parameter

```
create procedure procedureName()
BEGIN
    select * from register;
END //
```

⇨ Query with IN parameter

```
create procedure procedureName(IN empid INT)
BEGIN
    select * from register where id=empid;
END //
```

⇨ Query with In & OUT parameter

```
create procedure procedureName(IN empid
INT, OUT empname VARCHAR(25))
BEGIN
    select name into empname from register
    where id=empid;
END//
```

Steps to create JDBC application

1. Stored Procedure should be created
2. Load and register Driver
3. Create Connection
4. Create CallableStatement object and provide procedure call query
5. If IN parameter exists, then set values for In type parameter
6. If OUT parameter exists, then register OUT type parameter with a perticular data type
7. Create ResultSet object or simply print the values
